## Structure of the Talk

- Learning With Errors (Motivations from Post-Quantum Cryptography)
- RLWE and PLWE
- When are RLWE \& PLWE Equivalent?
- Previous Results (for Cyclotomic Polynomial)
- Our Contribution
- Sketch of the Proofs
- Open Questions

## Post-Quantum Cryptography

The first and most widely used public-key cryptosystem is RSA, which was invented by Rivest, Shamir, and Adleman in 1977. (An equivalent cryptosystem was developed in secret by Clifford Cocks in 1973 for the British signals intelligence agency and declassified in 1997.)

The security of RSA is based on the difficulty of integer factorization, that is, the problem of finding the prime factors of large integers.

No efficient (classical) algorithm to factorize large integers is known.
However, in 1994 Peter Shor invented a quantum algorithm, now known as Shor's algorithm, that can factorize integers in polynomial time by using a quantum computer.

## Post-Quantum Cryptography

Due to the recent progress and the large investments into the development of quantum computers, an actual implementation of Shor's algorithm constitutes a real threat to RSA.

Consequently, a lot of effort is put into post-quantum cryptography, that is, public-key cryptography designed to be resistant even against attacks using quantum computers.

Candidates for Post-Quantum Cryptography includes:

- Multivariate Cryptography
- Code-based Cryptography
- Hash-based Cryptography
- Lattice-based Cryptography
- Supersingular Elliptic Curve Isogeny Cryptography

## Lattice-Based Cryptography

Lattice-Based Cryptography relies its security on the difficulty of problems related to lattices, that is, subsets of $\mathbb{R}^{n}$ of the form $\left\{\sum_{i=1}^{k} x_{i} v_{i}: x_{i} \in \mathbb{Z}\right\}$ where $v_{1}, \ldots, v_{k} \in \mathbb{R}^{n}$.

It began in 1996 with the seminal work of Ajtai, who gave the first collision-resistant hash function on random lattices.

Since then, numerous lattice-based encryption and digital signature schemes have been proposed.

In particular, after a 5-year competion, in 2022 the National Institute of Standard and Technology decided to standardize three post-quantum digital signatures: CRYSTALS-Dilithium, Falcon, and SPHINCS+, of which the first two are lattice-based (the third is hash-based).

## Lattice-Based Cryptography

The main building block of lattice-based cryptographic schemes is the Learning With Errors (LWE) problem, which, roughly speaking, consists of retrieving a secret vector from a noisy random sample of matrix products.

## Learning With Errors (LWE) Problem

Let $n, m, q \in \mathbb{N}$ and $D$ be a probability distribution over $\mathbb{Z}_{q}:=\mathbb{Z} / q \mathbb{Z}$.
Given $m$ samples ( $\boldsymbol{a}_{i}, \boldsymbol{a}_{i} \cdot \boldsymbol{s}+e_{i}$ ) where $\boldsymbol{a}_{i} \in \mathbb{Z}_{q}^{n}$ are uniformly distributed random vectors, $e_{i} \in \mathbb{Z}_{q}$ are $D$-distributed random errors $(i=1, \ldots, m)$, and $s \in \mathbb{Z}_{q}^{n}$ is a secret vector; Find the secret vector $\boldsymbol{s}$.

LWE-based schemes have solid theoretical security bases but require the ciphertext or the public key to be nearly quadratic respect to the security parameters. To overcome this, variants of LWE working over $\mathbb{Z}_{q}[X] /(f)$, $f \in \mathbb{Z}_{q}[X]$, instead of $\mathbb{Z}_{q}^{n}$ have been introduced.

RLWE \& PLWE

## RLWE \& PLWE

In 2009, Stehlé et al. [1] introduced the Polynomial-LWE (PLWE) variant using power-of-two degree cyclotomic polynomials.

In 2010, Lyubashevsky et al. [2] introduced the Ring-LWE (RLWE) variant over the ring of integers of a number field.

The advantage of RLWE is the provable-security (as for LWE).
PLWE is preferable in implementations, where the modular arithmetic of polynomials can be efficiently implemented.

Therefore, it is interesting to study for which families of polynomials $f$ the RLWE and PLWE problems are "equivalent", that is, roughly speaking, every solution of RLWE can be turned in polynomial time into a solution of PLWE, and vice versa, incurring in a noise increase that is polynomial in $\operatorname{deg}(f)$.

When are RLWE \& PLWE Equivalent?
(The Formal Definition)

## Short Elements

Let $K=\mathbb{Q}(\alpha)$ be a monogenic number field of degree $m$, and let $f \in \mathbb{Z}[X]$ be the minimal polynomial of $\alpha$ over $\mathbb{Q}$, so that $K \cong \mathbb{Z}[X] /(f)$.

The geometric notion of short element derives from the choice of a norm on $K$ by embedding the number field in $\mathbb{C}^{m}$.

RLWE uses the canonical embedding $\sigma: K \rightarrow \mathbb{C}^{m}$, where $\sigma_{1}, \ldots, \sigma_{m}$ are all the embeddings of $K$ in $\mathbb{C}$.

PLWE uses the coefficient embedding, which maps $x \in K$ to the vector $\left(x_{0}, \ldots, x_{m-1}\right)$ of its coefficients respect to the power basis $1, \alpha, \ldots, \alpha^{m-1}$ of $K$ over $\mathbb{Q}$.

As a linear map, the canonical embedding has a matrix representation $V_{f} \in \mathbb{C}^{m \times m}$, so that $\sigma(x)=V_{f} \cdot\left(x_{0}, \ldots, x_{m-1}\right)^{\top}$ for each $x \in K$.

## Vandermonde Matrix

Precisely, $V_{f}$ is the Vandermonde matrix of $f$, which is defined as

$$
V_{f}:=\left(\begin{array}{ccccc}
1 & \alpha_{0} & \alpha_{0}^{2} & \cdots & \alpha_{0}^{m-1} \\
1 & \alpha_{1} & \alpha_{1}^{2} & \cdots & \alpha_{1}^{m-1} \\
1 & \alpha_{2} & \alpha_{2}^{2} & \cdots & \alpha_{2}^{m-1} \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
1 & \alpha_{m-1} & \alpha_{m-1}^{2} & \cdots & \alpha_{m-1}^{m-1}
\end{array}\right)
$$

where $\alpha_{0}, \ldots, \alpha_{m}$ are the roots of $f$ (which are distinct, since $f$ is irreducible).
It is well known that

$$
\operatorname{det}\left(V_{f}\right)=\prod_{0 \leq i<j<m}\left(\alpha_{i}-\alpha_{j}\right) \neq 0 .
$$

Hence $V_{f}$ is invertible.

## Equivalence Between RLWE and PLWE

Let $\|\cdot\|$ be any fixed norm on $\mathbb{C}^{m}$ (since all such norms are equivalent).
For the equivalence between RLWE and PLWE, it is important to determine when, whether $\|x\|$ is small, then so is $\|\sigma(x)\|$, and vice versa. This notion is quantified by $V_{f}$ having a small condition number $\operatorname{Cond}\left(V_{f}\right)$.

The condition number of an invertible matrix $A \in \mathbb{C}^{m \times m}$ is defined as

$$
\operatorname{Cond}(A):=\|A\|\left\|A^{-1}\right\|
$$

where $\|A\|:=\sqrt{\operatorname{Tr}\left(A^{*} A\right)}=\sqrt{\sum_{i, j}\left|a_{i, j}\right|^{2}}$ denotes the Frobenius norm of $A$, while $A^{*}$ is the conjugate transpose of $A$.

RLWE and PLWE are equivalent over a family of polynomials $\mathcal{F}$ if

$$
\operatorname{Cond}\left(V_{f}\right) \leq C_{\mathcal{F}}(\operatorname{deg}(f))^{E_{\mathcal{F}}}, \quad \text { for all } f \in \mathcal{F}
$$

where $C_{\mathcal{F}}, E_{\mathcal{F}}>0$ are constants depending only on the family $\mathcal{F}$.

Previous Results for Cyclotomic Polynomials

## Cyclotomic Polynomials

Equivalence of RLWE and PLWE has been proved for various families of polynomials.
The greatest interest concerns cyclotomic polynomials, which, for efficiency reasons, are among the most used in cryptographic applications.

Let us recall that the $n$th cyclotomic polynomial is defined as

$$
\Phi_{n}(X):=\prod_{\substack{1 \leq k \leq n \\ \operatorname{gcd}(n, k)=1}}\left(X-e^{2 \pi i k / n}\right),
$$

that is, $\Phi_{n}(X)$ is the monic polynomial having as roots the primitive $n$th roots of unity.
It can be proved that $\Phi_{n}$ has integer coefficients and is irreducible over $\mathbb{Q}$. In fact, $\Phi_{n}$ is the minimal polynomial of each primitive $n$th root of unity.

In what follows, let $m:=\varphi(n)$ be the degree of $\Phi_{n}$, where $\varphi$ is the Euler totient function, and let $\zeta_{0}, \ldots, \zeta_{m-1}$ be the primitive $n$th roots of unity (in some fixed order), where, to ease the notation, the dependency on $n$ is omitted.

## Vandermonde Matrices of Cyclotomic Polynomials

Thus the Vandermonde matrix of $\Phi_{n}$ is

$$
V_{n}:=V_{\Phi_{n}}=\left(\begin{array}{ccccc}
1 & \zeta_{0} & \zeta_{0}^{2} & \cdots & \zeta_{0}^{m-1} \\
1 & \zeta_{1} & \zeta_{1}^{2} & \cdots & \zeta_{1}^{m-1} \\
1 & \zeta_{2} & \zeta_{2}^{2} & \cdots & \zeta_{2}^{m-1} \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
1 & \zeta_{m-1} & \zeta_{m-1}^{2} & \cdots & \zeta_{m-1}^{m-1}
\end{array}\right)
$$

The main difficulty in the study of $V_{n}$ is that the sequence of powers $1, \quad \zeta_{j}, \quad \zeta_{j}^{2}, \quad \zeta_{j}^{3}, \quad \ldots$
is periodic with period length $n$, but $V_{n}$ has only $m$ columns and $m<n$.
Note that $\left\|V_{n}\right\|=m$, since $\left|\zeta_{j}\right|=1$. Therefore, computing the condition number Cond $\left(V_{n}\right):=\left\|V_{n}\right\|\left\|V_{n}^{-1}\right\|$ boils down to computing $\left\|V_{n}^{-1}\right\|$.

## The Power-of-Two Case

## Proposition

For $n=2^{k}$ the matrix $V_{n}$ is a scaled isometry: $V_{n} V_{n}^{*}=m I_{n}$, where $I d_{n}$ is the $n \times n$ identity matrix. Furthermore, we have that $\operatorname{Cond}\left(V_{n}\right)=m$.

Proof: Since $n=2^{k}$, we have that $m=2^{k-1}$ and $\zeta_{i}^{m}=-1$ for each $i$. Hence, the product of the $i$ th row of $V_{n}$ and the $j$ th column of $V_{n}^{*}$ is equal to $m$ if $i=j$, and it is equal to

$$
\sum_{k=0}^{m-1}\left(\zeta_{i} \overline{\zeta_{j}}\right)^{k}=\frac{\left(\zeta_{i} \bar{\zeta}_{j}\right)^{m}-1}{\zeta_{i} \overline{\zeta_{j}}-1}=0
$$

if $i \neq j$; so that $V_{n} V_{n}^{*}=m \operatorname{ld}_{n}$ and consequently $\operatorname{Cond}\left(V_{n}\right)=m$.

## Corollary

RLWE and PLWE over the polynomial family $\left(\Phi_{2^{k}}\right)_{k \geq 1}$ are equivalent.

## Some Upper Bounds on Cond $\left(V_{n}\right)$

## Theorem (Blanco-Chacón 2020 [3])

Let $n=p_{1} \cdots p_{k}$, where $p_{1}<\cdots<p_{k}$ are prime numbers. Then

$$
\operatorname{Cond}\left(V_{n}\right) \leq 2 p_{1} \cdots p_{k} n^{2^{k}+2^{k-1}+k+2}
$$

## Corollary

For every fixed $k \geq 1$, RLWE and PLWE over the polynomial family $\left(\Phi_{p_{1} \cdots p_{k}}\right)_{p_{1}<\cdots<p_{k}}$ are equivalent.

## Some Upper Bounds on Cond $\left(V_{n}\right)$

## Theorem (Blanco-Chacón 2020 [3])

Let $p_{1}<p_{2}<p_{3}$ be prime numbers and let $e_{1}, e_{2}, e_{3} \geq 1$ be integers.

- For $n=p_{1}^{e_{1}}$ we have that

$$
\operatorname{Cond}\left(V_{n}\right) \leq 4 \varphi\left(p_{1}\right) m
$$

- For $n=p_{1}^{e_{1}} p_{2}^{e_{2}}$ we have that

$$
\operatorname{Cond}\left(V_{n}\right) \leq 2 \varphi\left(p_{1} p_{2}\right) m^{2}
$$

- For $n=p_{1}^{e_{1}} p_{2}^{e_{2}} p_{3}^{e_{3}}$ we have that

$$
\operatorname{Cond}\left(V_{n}\right) \leq 2\left(\varphi\left(p_{1} p_{2} p_{3}\right)\right)^{2} m^{2}
$$

## Our Contribution

## Reduction to Squarefree Numbers

## Theorem (Di Scala, S., Signorini 2021 [4])

For every positive integer $n$, we have

$$
\operatorname{Cond}\left(V_{n}\right)=\frac{n}{\operatorname{rad}(n)} \operatorname{Cond}\left(V_{\operatorname{rad}(n)}\right)
$$

where $\operatorname{rad}(n)$ is the product of the prime factors of $n$.

Hence, in the study of Cond $\left(V_{n}\right)$, it suffices to consider only squarefree $n$.

## Exact Formula for $\operatorname{Cond}\left(V_{n}\right)$ when $n=p^{k}$ and $n=2^{k} p^{h}$

## Theorem (Di Scala, S., Signorini 2021 [4])

For $n=p^{k}$, with $k \geq 1$ and $p$ a prime number, and for $n=2^{k} p^{h}$, with $k, h \geq 1$ and $p$ an odd prime number, we have that

$$
\operatorname{Cond}\left(V_{n}\right)=\sqrt{2(1-1 / p)} m
$$

Note that this exact formula improves the previous upper bound for $n=p^{k}$

$$
\operatorname{Cond}\left(V_{n}\right) \leq 4(p-1) m,
$$

given by Blanco-Chacón.

## Non-Equivalence of RLWE and PLWE over $\left(\Phi_{n}\right)$

## Theorem (Di Scala, S., Signorini 2022 [5])

There exist infinitely many positive integers $n$ such that

$$
\operatorname{Cond}\left(V_{n}\right)>\exp \left(n^{\log 2 / \log \log n}\right) / \sqrt{n}
$$

In particular, for every $E>0$, we have that $\operatorname{Cond}\left(V_{n}\right) \neq O\left(n^{E}\right)$.

## Corollary

RLWE and PLWE over cyclotomic fields are not equivalent.

A plot of $\operatorname{Cond}\left(V_{n}\right)$ with $n$ squarefree, $1<n<10000$. The data is partitioned according to the number $\omega(n)$ of prime factors of $n$.
(Edoardo Signorini: https://github.com/edoars/cyclovandermonde)

## Sketch of the Proofs: First Results

## Ramanujan's Sums

The Ramanujan's sum modulo $n$ is the arithmetic function $c_{n}$ defined by

$$
c_{n}(t):=\sum_{j=0}^{m-1} \zeta_{j}^{t}, \quad \text { for all } t \in \mathbb{Z}
$$

(Recall that $\zeta_{0}, \ldots, \zeta_{m-1}$ are the primitive $n$th roots of unity.)
It is easy to check that $c_{n}$ is an even periodic function with period length $n$.
Furthermore, it holds the von Sterneck formula

$$
c_{n}(t)=\mu\left(\frac{n}{(n, t)}\right) \frac{\varphi(t)}{\varphi\left(\frac{n}{(n, t)}\right)}
$$

where $\mu$ is the Möbius function and ( $n, t$ ) denotes the greatest common divisor. In particular, $c_{n}(t)$ is an integer.

## Gram Matrix of $V_{n}$

Let $G_{n}:=V_{n}^{*} V_{n}$ be the Gram matrix of $V_{n}$. Then we have

$$
G_{n}=\left(\begin{array}{cccc}
c_{n}(0) & c_{n}(1) & \cdots & c_{n}(m-1) \\
c_{n}(1) & c_{n}(0) & \cdots & c_{n}(m-2) \\
\vdots & \vdots & \ddots & \vdots \\
c_{n}(m-1) & c_{n}(m-2) & \cdots & c_{n}(0)
\end{array}\right)=\left(c_{n}(i-j)\right)_{0 \leq i, j<m} .
$$

In particular, $G_{n}$ is a symmetric Toeplitz matrix with integer entries.
Let $\lambda_{1}, \ldots, \lambda_{m}$ be the eigenvalues of $G_{n}$, which are real and positive, since $G_{n}$ is the Gram matrix of an invertible matrix. Then

$$
\operatorname{Cond}\left(V_{n}\right)=\left\|V_{n}\right\|\left\|V_{n}^{-1}\right\|=m \sqrt{\operatorname{Tr}\left(G_{n}^{-1}\right)}=m \sqrt{\sum_{i=1}^{m} \frac{1}{\lambda_{i}}}
$$

Hence, studying Cond $\left(V_{n}\right)$ is equivalent to studying the eigenvalues of $G_{n}$.

## Reduction to Squarefree Numbers

## Lemma

For every positive integer n, we have

$$
\operatorname{det}\left(G_{n}-x \operatorname{Id}_{m}\right)=h^{m} \operatorname{det}\left(G_{n^{\prime}}-\frac{x}{h} \operatorname{Id}_{m^{\prime}}\right)^{h}
$$

where $n^{\prime}:=\operatorname{rad}(n), m^{\prime}:=\varphi\left(n^{\prime}\right)$, and $h:=n / n^{\prime}$.
Proof (Sketch): von Sterneck formula yields that $G_{n}=h G_{n^{\prime}} \otimes \mathrm{Id}_{h}$. Then one uses $\operatorname{det}(A \otimes B)=\operatorname{det}(A)^{s} \operatorname{det}(B)^{t}$, for $A \in \mathbb{C}^{t \times t}$ and $B \in \mathbb{C}^{s \times s}$. $\square$

Thus the eigenvalues of $G_{n}$ are the eigenvalues of $G_{\text {rad }(n)}$ multiplied by $h$ both in values and multiplicities. Hence, from the previous considerations, it follows that

$$
\operatorname{Cond}\left(V_{n}\right)=\frac{n}{\operatorname{rad}(n)} \operatorname{Cond}\left(V_{\operatorname{rad}(n)}\right)
$$

## The Cases $n=p^{k}$ and $n=2^{k} p^{h}$

Further work with von Sterneck formula shows that $G_{2 n}$ and $G_{n}$ have the same eigenvalues, for every odd positive integer $n$.
Therefore, the computation of the condition number $\operatorname{Cond}\left(V_{n}\right)$ for $n=p^{k}$ and $n=2^{k} p^{h}$ is reduced to the computation of $\operatorname{Cond}\left(V_{p}\right)$.

Since

$$
G_{p}=\left(\begin{array}{ccccc}
p-1 & -1 & -1 & \cdots & -1 \\
-1 & p-1 & -1 & \cdots & -1 \\
-1 & -1 & p-1 & \cdots & -1 \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
-1 & -1 & -1 & \cdots & p-1
\end{array}\right)
$$

a bit of computation shows that the eigenvalues of $G_{p}$ are $p$ and 1 , with respective multiplicities $p-2$ and 1 .
From this, one gets the formulas for $\operatorname{Cond}\left(V_{p^{h}}\right)$ and $\operatorname{Cond}\left(V_{2^{k} p^{h}}\right)$.

Sketch of the Proofs:
Lower Bound for Cond $\left(V_{n}\right)$

## The Proof of the Lower Bound for Cond $\left(V_{n}\right)$

The main difficulty in proving a lower bound for $\operatorname{Cond}\left(V_{n}\right)$ is that the entries of $V_{n}^{-1}$ are sums of many roots of unity, but in such sums a lot of "cancellation" can happen.

This is strictly related to the fact that the coefficients of the cyclotomic polynomials are usually small, despite being sums of many roots of unity.

Lehmer (1966) gave the following enlightening example: Expanding the product

$$
\Phi_{105}(X):=\prod_{\substack{1 \leq k \leq 105 \\ \operatorname{gcd}(105, k)=1}}\left(X-\mathrm{e}^{2 \pi i k / 105}\right)
$$

one gets that the coefficient of $X^{7}$ in $\Phi_{105}(X)$ is the sum of

$$
\binom{48}{7}=73,629,072
$$

roots of unity. Despite that, such a coefficient is equal to -2 .

## Continuing $V_{n}$

Let

$$
W_{n}:=\left(\begin{array}{ccccc}
1 & \zeta_{0} & \zeta_{0}^{2} & \cdots & \zeta_{0}^{m n-1} \\
1 & \zeta_{1} & \zeta_{1}^{2} & \cdots & \zeta_{1}^{m n-1} \\
1 & \zeta_{2} & \zeta_{2}^{2} & \cdots & \zeta_{2}^{m n-1} \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
1 & \zeta_{m-1} & \zeta_{m-1}^{2} & \cdots & \zeta_{m-1}^{m n-1}
\end{array}\right)
$$

be the $m \times m n$ matrix obtained by "continuing" $V_{n}$ to the right.

## Lemma

We have $W_{n} W_{n}^{*}=m n \operatorname{ld}_{m}$.
Proof: The product of the $i$ th row of $W_{n}$ and the $j$ th column of $W_{n}^{*}$ is

$$
\sum_{k=0}^{m n-1}\left(\zeta_{i} \overline{\zeta_{j}}\right)^{k}= \begin{cases}m n & \text { if } i=j \\ 0 & \text { if } i \neq j\end{cases}
$$

(This is the orthogonality of roots of unity.) $\square$.

## Coefficients of $\Phi_{n}$

Let $a_{n}(j)$ denote the coefficient of $X^{j}$ in $\Phi_{n}(X)$, that is,

$$
\Phi_{n}(X)=\sum_{j=0}^{m} a_{n}(j) X^{j}
$$

The study of the coefficients of the cyclotomic polynomials has a very long history, which goes back at least to Gauss (see [6] for a survey).

Let $A(n)$ be the maximum of the absolute values of $a_{n}(0), \ldots, a_{n}(m-1)$.

## Theorem (Vaughan 1974 [7])

We have $A(n)>\exp \left(n^{\log 2 / \log \log n}\right)$ for infinitely many positive integers $n$.

A plot of the coefficients of $\Phi_{n}(X)$ for $n=3 \cdot 5 \cdot 7 \cdot 11 \cdot 13 \cdot 17 \cdot 19 \cdot 23 \cdot 29$. The $\varphi(n)+1=$ $1,021,870,081$ coefficients were computed using the program SPS4_64 of Arnold and Monagan [8]. The plot was produced by selecting a random sample of 500,000 coefficients.

## Companion Matrix of $\Phi_{n}$

Let $C_{n}$ be the companion matrix of $\Phi_{n}$, which is the $m \times m$ matrix

$$
C_{n}:=\left(\begin{array}{ccccc}
0 & 0 & \cdots & 0 & -a_{n}(0) \\
1 & 0 & \cdots & 0 & -a_{n}(1) \\
0 & 1 & \cdots & 0 & -a_{n}(2) \\
\vdots & \vdots & \ddots & \vdots & \vdots \\
0 & 0 & \cdots & 1 & -a_{n}(m-1)
\end{array}\right),
$$

and let

$$
S_{n}:=\left(\operatorname{ld}_{m}\left|C_{n}^{m}\right| C_{n}^{2 m}|\cdots| C_{n}^{(n-1) m}\right)
$$

be the $m \times m n$ matrix given by juxtapositioning the first $n$ powers of $C_{n}^{m}$.

## Lemma

We have $V_{n}^{-1} W_{n}=S_{n}$.
Proof (Hint): It is due to the fact that $\zeta_{k}^{m}=-\sum_{j=0}^{m-1} a_{n}(j) \zeta_{k}^{j}$, since $\Phi_{n}\left(\zeta_{k}\right)=0 . \square$

## A Formula for $\left\|V_{n}^{-1}\right\|$

## Lemma

We have $\left\|V_{n}^{-1}\right\|^{2}=\frac{1}{m n} \sum_{k=0}^{n-1}\left\|C_{n}^{k m}\right\|^{2}$.
Proof: From $W_{n} W_{n}^{*}=m n \operatorname{ld}_{m}$ and $V_{n}^{-1} W_{n}=S_{n}$, it follows that

$$
m n\left\|V_{n}^{-1}\right\|^{2}=m n \operatorname{Tr}\left(V_{n}^{-1}\left(V_{n}^{-1}\right)^{*}\right)=\operatorname{Tr}\left(V_{n}^{-1} W_{n} W_{n}^{*}\left(V_{n}^{-1}\right)^{*}\right)=\operatorname{Tr}\left(S_{n} S_{n}^{*}\right)
$$

Then, by the definition of $S_{n}$, we have that

$$
\begin{aligned}
& \operatorname{Tr}\left(S_{n} S_{n}^{*}\right)=\operatorname{Tr}\left(\left(\left|\mathrm{d}_{m}\right| C_{n}^{m}|\cdots| C_{n}^{(n-1) m}\right)\left(\frac{\frac{d_{m}}{\left(C_{n}^{m}\right)^{*}}}{\frac{\vdots}{\left(C_{n}^{(n-1) m}\right)^{*}}}\right)\right) \\
& = \\
& \sum_{k=0}^{n-1} \operatorname{Tr}\left(C_{n}^{k m}\left(C_{n}^{k m}\right)^{*}\right)=\sum_{k=0}^{n-1}\left\|C_{n}^{k m}\right\|^{2}
\end{aligned}
$$

## Powers of the Companion Matrix $C_{n}$

## Lemma

Let $k$ be a positive integer and let

$$
C:=\left(\begin{array}{ccccc}
0 & 0 & \cdots & 0 & c_{0} \\
1 & 0 & \cdots & 0 & c_{1} \\
0 & 1 & \cdots & 0 & c_{2} \\
\vdots & \vdots & \ddots & \vdots & \vdots \\
0 & 0 & \cdots & 1 & c_{k-1}
\end{array}\right) \in \mathbb{C}^{k \times k} .
$$

Then, for every integer $j \in[1, k]$, the $(k-j)$ th column of $C^{j}$ is equal to $\left(\begin{array}{llll}c_{0} & c_{1} & \cdots & c_{k-1}\end{array}\right)^{\top}$. (Note: The first column if the 0th.)

Proof: Actually, a stronger claim holds: For every integer $j \in[1, k]$, the 0 th, 1 th, $\ldots$, $(k-j)$ th columns of $C^{j}$ are equal to the $(j-1)$ th, $j$ th, $\ldots,(k-1)$ th columns of $C$, respectively. This follows easily by induction on $j$.

## The Lower Bound for Cond $\left(V_{n}\right)$

Putting all together, we get that

$$
\left\|V_{n}^{-1}\right\|^{2}=\frac{1}{m n} \sum_{k=0}^{n-1}\left\|C_{n}^{k m}\right\|^{2} \geq \frac{1}{m n}\left\|C_{n}^{m}\right\|^{2} \geq \frac{1}{m n} \sum_{j=0}^{m-1}\left|a_{n}(j)\right|^{2} \geq \frac{1}{m n} A(n)^{2}
$$

where in the second inequality we used the previous lemma (since $m<n$ ).
In turn, this implies that

$$
\operatorname{Cond}\left(V_{n}\right)=\left\|V_{n}\right\|\left\|V_{n}^{-1}\right\|=m\left\|V_{n}^{-1}\right\| \geq \sqrt{\frac{m}{n}} A(n) \geq \frac{1}{\sqrt{n}} A(n)
$$

As a consequence, Vaughan's lower bound for $A(n)$ yields that

$$
\operatorname{Cond}\left(V_{n}\right)>\exp \left(n^{\log 2 / \log \log n}\right) / \sqrt{n}
$$

for infinitely many positive integers $n$. The proof is complete.

## Open Questions

## Open Questions

- Is there an "explicit formula" for $\operatorname{Cond}\left(V_{p q}\right)$ (equivalently, for $\left.\left\|V_{p q}^{-1}\right\|\right)$ for $p, q$ primes ?
- What is the maximal order of $\operatorname{Cond}\left(V_{n}\right)$ (equivalently, of $\left\|V_{n}^{-1}\right\|$ ) as $n \rightarrow+\infty$ ?
- What about RLWE-PLWE equivalence for other families of polynomials / number fields ? For instance, Blanco-Chacón [9] considered the maximal totally real subextension of the $4 p$ th cyclotomic field.
